

Epigenetics play a significant role in growth, development, and disease progression.

Fios Genomics provides a range of epigenetic analysis services, including DNA methylation profiling, miRNA profiling and ChIP-on-chip analysis, to help to identify the factors regulating expression of genes or biomarkers implicated in many disease processes or drug response.

DNA methylation is a common subject of investigations into responses to disease and aging as well as agrogenomic studies into drought, temperature extremes, and other environmental changes.

Our service offerings are perfect for both newcomers to epigenetics as well as high-throughput labs that want to utilize our long history of expertise in this area.
